

## Film Industry Analysis & Insights

John Paul Hernandez Alcala

Hello, my name is John Paul, and I am a data scientist with DataCorp. Today my goal is to give you a better understanding of the movie industry. Let's get started!

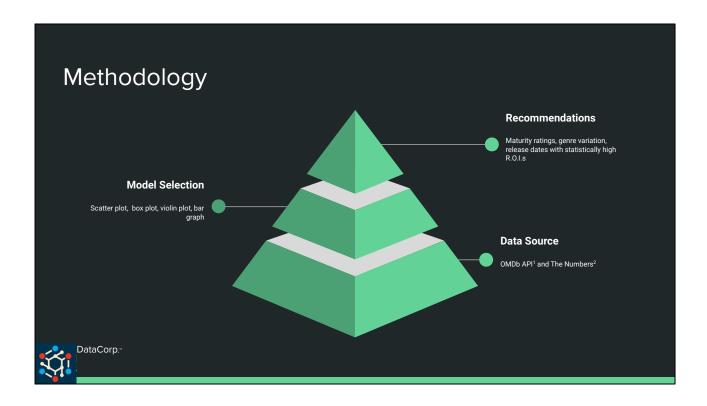

Before we dive into the analysis of the film industry, we have to present ourselves with three questions that make up our problem statement: define a financially successful film, types of successful films, and derive actionable insights.

## **Business Value** Worldwide Return on Investment (R.O.I.) Accounts for net income (i.e. production Define a financially successful cost) Small production budget friendly Quick and powerful comparisons Maturity Rating Types of successful films Genre Variation Release Date Maturity ratings with statistically high R.O.I.s Derive actionable insights Genre variations with statistically high R.O.I.s Release date with statistically high R.O.I.s DataCorp.

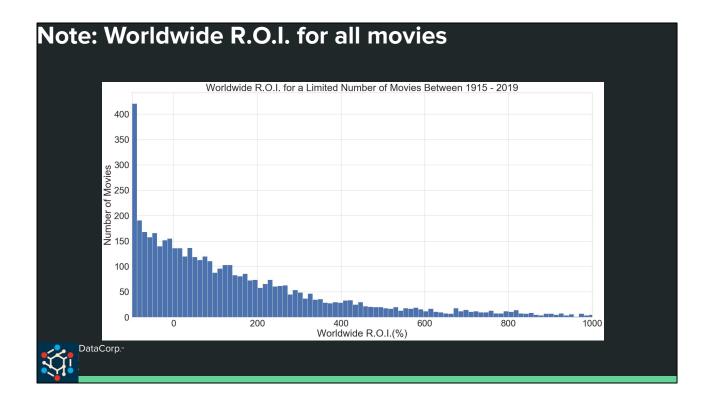

To better answer these questions, we must equip ourselves with the right tools to build towards a viable and reasonable conclusion. For the 1st question, we will use the overall median value to the top 25% Worldwide Return on Investment (R.O.I.) because it takes into account net income, it is friendly to small production budgets, and it allows for quick and powerful comparisons.

In our case, R.O.I. is calculated as such: (Worldwide Gross - Production Budget) / Production Budget  $\times$  100 = R.O.I (%)

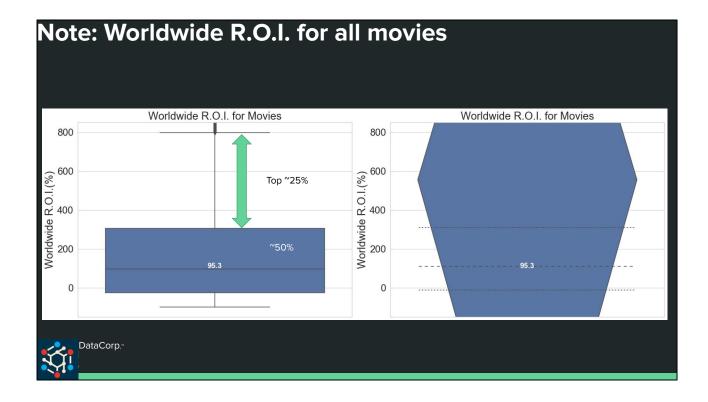

For the 2nd question, we will limit ourselves to the maturity rating, genre variation, and release date of successful movies. Finally for question 3, we will obtain recommendations for specific maturity ratings, genre variations, and release dates.

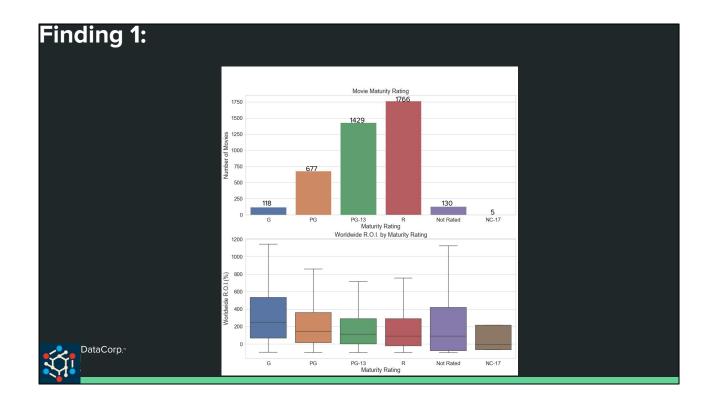

With the tools in place, we are able to build our foundation off the data we collect from OMDb and The Numbers, work our way up with statistical models such as scatter plots, box plots, violin plots, and bar graphs, and finally arrive to our recommendations.

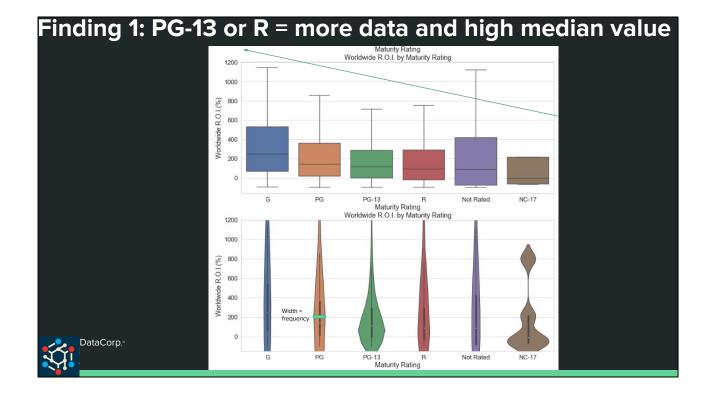

To start our analysis, we need to figure out how Worldwide R.O.I. is distributed, and, from the figure here, we can tell it is not evenly distributed at all.

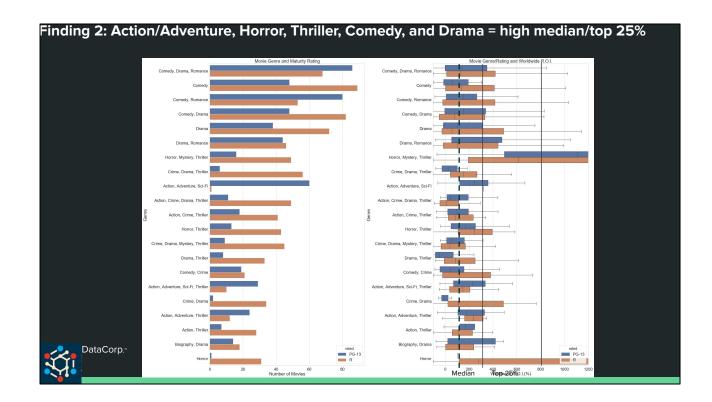

So we must look to quantifying our data with a box plot. With this plot, we can see that the R.O.I. value of about 99.7% of our movies fall between -50% and 800%. The 95.3% is the median R.O.I. value for all the movies. The 50% signifies that 50% of our data resides in the box which starts slightly below zero and ends around 350%. We will be using this graph as a metric of success for the comparisons to come. More specifically, the goal is find a maturity rating, genre variation, and release date with R.O.I. values that fall between 95.3% and 800% because 95.3% acts as our 'average' R.O.I. value whereas 800% acts as our maximum.

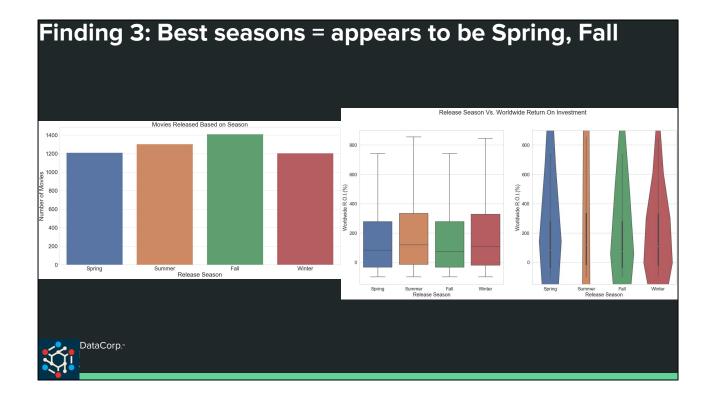

From our analysis of maturity ratings, 'PG-13' and 'R' has the most data, and 'G' rated has the highest median R.O.I. value and 75% of its movies have a R.O.I. value above ~75% followed by 'PG', 'PG-13', 'R'-tied-'Not Rated', and 'NC-17'; however, 'R' rated movies are made the most followed by 'PG-13', 'PG', 'Not Rated', 'G', and 'NC-17'

On this next set of graphs, we observe that rated 'PG-13' and 'R' movies have more R.O.I.'s values around their respective median value which suggest predictability. Although it would seem logical to select 'G' or 'PG', the amount of movies released for these two ratings only accounts for ~20% of the data; therefore, it is recommendable to design a movie with 'PG-13' or 'R' rating because of its predictability and amount of movies released with these ratings. This means Microsoft can expect an R.O.I. value around 100% - 150% for movies rated at 'PG-13' or 'R' which is within our goal.

We now take a look at genre, and we immediately notice genre for a movie is rarely limited to only one. Therefore, genre variations were analyzed instead. Of the genre variations, common genres that have more than the median R.O.I. movie value of 95.3% are Action/Adventure, Horror, Thriller, Comedy, and Drama. It is recommendable to design a movie with Action/Adventure, Horror, Thriller, Comedy, and Drama features in it because these genres have more than the median R.O.I. movie value of 95.3% or reach into the top 25%. This means Microsoft can expect an R.O.I. value around 95.3% - 350% for movies with Action/Adventure, Horror, Thriller, Comedy, and Drama features which is within our goal.

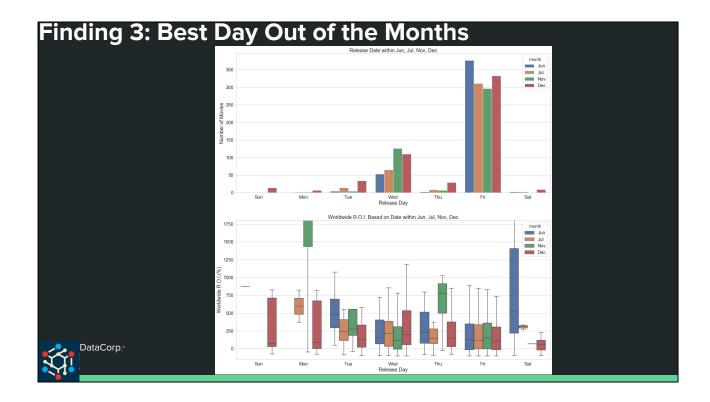

Moving next to seasons, we see that all seasons release about the same number of movies; Thus, R.O.I. distribution could be used for comparison. The season with highest median R.O.I. value is Summer followed by Winter, spring, and Fall. Although Summer and Winter have high median R.O.I. values, the frequency of movies that achieved around their respective median R.O.I. value is less certain than with the movies from Spring and Fall; in other words, movies released in Spring and Fall are more likely to have a R.O.I. that is close to the median R.O.I. value for Spring and Fall. This means Microsoft can expect an R.O.I. value ~95% - ~150% for movies released in Spring and Fall which is within our goal.

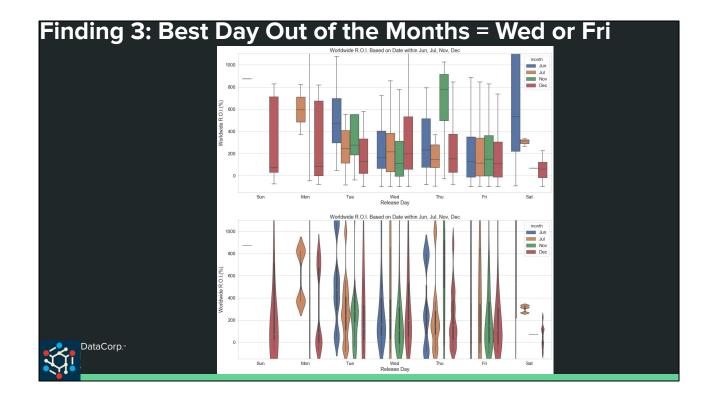

We push deeper into seasons by breaking down into months. The months release roughly about the same number of movies; therefore, just like seasons, the R.O.I. distribution could be used for comparison. The month with the highest median R.O.I. value is Nov, followed by Jul, Jun, Dec, May, Feb, Aug, Mar, Jan, Oct, April, and Sep.

Additionally, we found that Nov and Dec not only have high median R.O.I.s, but also the most reliable R.O.I. distributions because they are close to their respective median R.O.I. values. This means Microsoft can expect an R.O.I. value ~150% - ~180% for movies released in Nov and Dec which is within our goal.

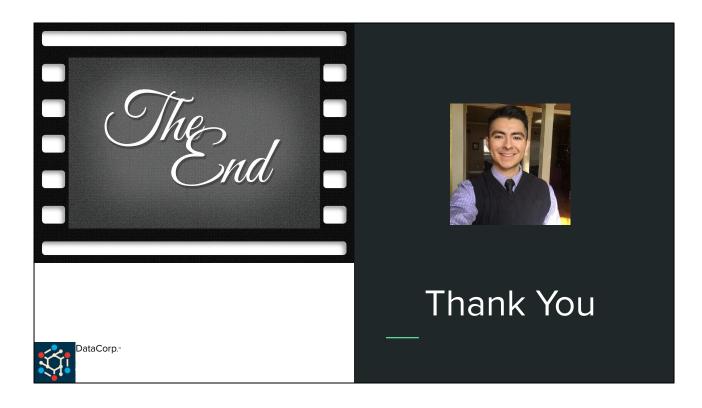

We analyze the days more closely in Jun, Jul, Nov, and Dec. We immediately notice that movies are predominantly released on Wed and Fri.

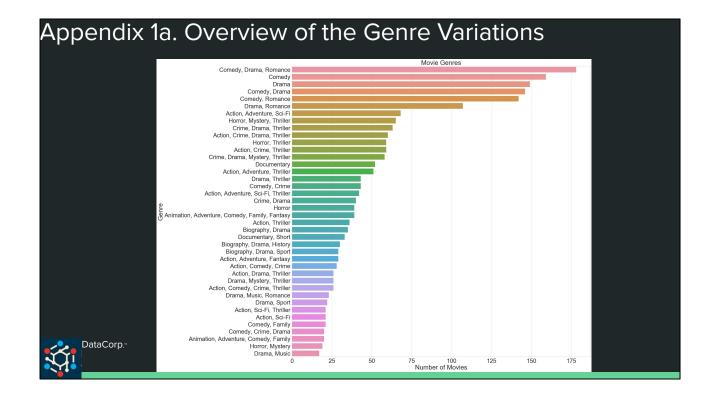

From the previous graphs and these graphs, we recommend that the best days to release a movie are on Wednesday or Friday because of high R.O.I. median values coupled with reliable R.O.I distributions that accumulate around their respective R.O.I. median values. This means Microsoft can expect an R.O.I. value  $\sim 150\%$  -  $\sim 180\%$  for movies released in Wed and Fri which is within our goal.

## **Future Work** Production Budget vs. Worldwide R.O.I.(%) Set a baseline budget Correlation analysis customer ratings vs. genre Supply demand Customer reviews on genre Isolate high impact components such as Genre specification explosions, music, etc for market targeting Production time for different genre variations More precise R.O.I. calculation More data Daily, weekly, monthly income from theaters How long should we have the movie out? DataCorp.

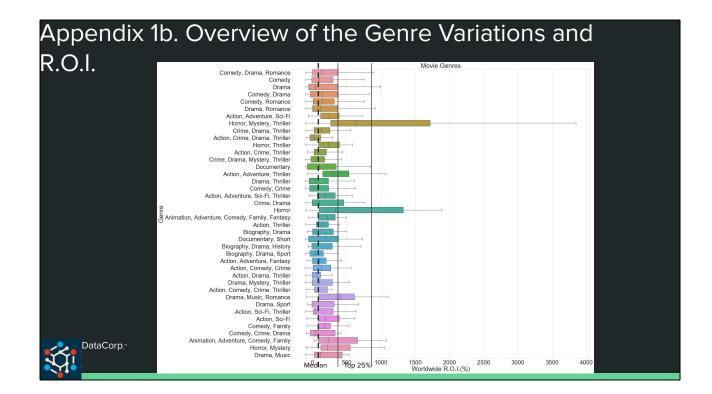

Now that we have heard all these recommendations, what now? We can do correlation analysis on production budget vs. worldwide R.O.I. (%), so we can establish a baseline budget for financial resource allocation. We can also do a correlation analysis on customer ratings vs. genre to address customer demands. Additionally, we can look at what specifics from a genre customers are looking for explosions, music, etc for market targeting. Finally, with more data, we can look at production time for different genre variations to make our R.O.I. calculation more accurate with net profit, and we can look at daily, weekly, monthly income from theaters so we can have a better idea when to pull a movie from the theater before suffering financial loss.

Thank you for your time! Please, feel free to ask me any questions at this time.

Here are the top 40 genres not constrained by maturity rating.

Here are the top 40 genres not constrained by maturity rating. The only genre with a median value in the top 25% is horror/mystery/thriller
